📄 Revenue Analytics – Explanation Note

1 Project Overview

This project builds an end-to-end revenue analytics solution using Power BI.
The objective is to clean transaction-level data, normalize pricing structures (Flat/%), compute ERP and Edviron revenue layers, and create an interactive financial dashboard with exposure tracking.
The model is designed to be dynamic, audit-friendly, and filter-aware.

---

2 Data Cleaning & Normalization

a) Date Standardization

The Date & Time column contained mixed formats including timezone values.
It was cleaned in Power Query by:

- Removing timezone components
- Standardizing format using locale conversion
- Converting to Date/Time type

---

b) Pricing Normalization (Flat vs %)

Pricing inputs were standardized into absolute INR per transaction.
For each transaction:

- If Pricing Type = FLAT
  → Value used directly.
- If Pricing Type = PERCENT
  → Transaction Amount × Pricing Rate / 100.

The following calculated columns were created:

- Merchant_INR
- Partner_INR
- EdvironBuying_INR

This ensures all revenue calculations operate on absolute INR values.

---

3 Revenue Logic

Revenue was computed using layered financial logic:

ERP Revenue

ERP Revenue = Partner_INR
(Only for successful transactions)

Edviron Gross Revenue

Edviron Gross Revenue = Merchant_INR − Partner_INR
Represents platform margin before gateway cost.

Edviron Net Revenue

Edviron Net Revenue =

Merchant_INR − Partner_INR − EdvironBuying_INR

Represents actual retained profit after gateway cost.

Profit Margin %

Profit Margin % =

Edviron Net Revenue ÷ ERP Revenue

---

4 Settlement & Exposure Logic

Settlement status was derived using Is_Success flag:

- Settled → Is_Success = 1
- Pending → Is_Success = 0

Pending Transaction Value and Settled Transaction Value measures were created.

Current dataset shows:

100% settled transactions (No pending exposure).

However, the model supports dynamic exposure tracking if pending transactions exist.

---

5 Dashboard Rationale

The dashboard is structured into five business-focused pages:

1. Dashboard

High-level KPI view:

- Total Volume
- ERP Revenue
- Gross & Net Revenue
- Profitability
- Settlement Distribution

Purpose: Executive summary.

---

2. Time Summary

Monthly revenue trends and ERP contribution over time.

Purpose: Identify growth patterns and seasonal variation.

---

3. Partner Performance

- ERP Revenue comparison
- Net Revenue comparison
- Profit Margin %

- Ranking
- Contribution %

Purpose: Evaluate partner profitability and concentration risk.

---

4. Gateway & Payment Method

- Revenue by gateway
- Volume distribution by payment method
- Gateway × Method breakdown

Purpose: Channel performance analysis.

---

5. Pending vs Settled Exposure

- Settlement KPIs
- Exposure distribution
- ERP-level risk analysis

Purpose: Financial risk monitoring.

---

6 Interactivity & Model Design

The model is fully dynamic using DAX measures and slicers:

Slicers included:

- Date range
- ERP Partner
- Gateway
- Payment Method

All visuals respond automatically to filters.

Measures were used instead of hard-coded values to ensure scalability and accuracy.

---

7 Assumptions

- Revenue is calculated only for successful transactions.
- Capture Status column was not fully populated; therefore, settlement logic is based on Status field.
- No pending transactions exist in current dataset.
- All pricing inputs are assumed accurate.
-
